Background: Vascularized Composite Allograft (VCA) transplantation is a treatment option for complex tissue injuries; however, ischemia reperfusion injury (IRI) and high acute rejection rates remain a challenge. Hypothermic machine perfusion (HMP) using acellular storage perfusate is a potential solution. This study evaluated the University of Wisconsin (UW) Kidney Preservation Solution (KPS-1) compared to normal saline (NS) for preservation of donor rat hind limbs subjected to 24h of ex-vivo perfusion cold storage.

Methods: Hind limbs were subjected to 24-hour perfusion cold storage with heparinized KPS-1 (n=6) or heparinized NS (n=6). Flow, resistance, and pH were measured continuously. At the end of the 24h period, tissue was collected for histological analysis of edema and apoptosis.
**Results:** KPS-1 perfused limbs showed significantly less edema than the NS group, as evidenced by lower limb weight gain (p<0.001) and less interfascicular space (p<0.001). KPS-perfused muscle had significantly less cell death than NS-perfused muscle based on terminal deoxynucleotidyl transferase dUTP nick-end labeling (TUNEL) (p<0.001) and Cleaved Caspase-3 (CC3) staining (p=0.045). During HMP, a significant decrease in pH over time was detected in both groups, with a significantly greater decline in pH in the KPS-1 group than in the NS group. There were no significant differences overall and over time in flow rate or vascular resistance between the KPS and NS groups.

**Conclusions:** Perfusion with KPS-1 can successfully extend VCA perfusion cold storage for 24h in a rat hind limb model without significant edema or cell death.
