

# INTRODUCTION

Ehlers-Danlos syndrome (EDS) is an inherited collagen disorder that, based on the subtype, comes with varying risks of life-threatening hemorrhage. The risk of postoperative adenotonsillectomy (T&A)/tonsillectomy hemorrhage should be scrutinized in patients with EDS. Better risk assessment will aid in medical optimization before surgery, counseling families of surgical risks, and may decrease admission costs in lower-risk EDS patients.

# BACKGROUND

https://www.compleowaco.com/ehlers-danlos-syndrome/

- EDS is characterized by joint hypermobility, skin hyperextensibility, easy bruising, and abnormal scarring(1).
- Caused by a COL5A1, COL5A2 mutation, or COL1A1 mutation in the arthrochalasia type, or COL3A1 mutation in the in vascular specific subtype. These affect type V collagen production leading to decreased tissue tensile strength(2).
- Sources of bleeding in EDS include GI bleeding, menorrhagia, intracranial hemorrhage, aneurism ruptures, and aortic dissection secondary to aortic root dilation(3).
- Von Willebrand (VWb) factor binds to type V collagen to induce clotting; hence, EDS patients may experience increased bleeding similar to VWb disorder, due to the inability of normal VWb factor to bind to abnormal collagen binding sites(4). • There is a paucity of data on post-op bleeding complication rates for EDS patients
- during routine surgical procedures, such as T&A.
- Assessing the risk of bleeding in EDS patients following T&A can lead to informed decision-making around admitting this patient population following any surgical procedure, which could save families unnecessary costs(5).

# HYPOTHESIS

Children with EDS experience increased rates of post adenotonsillectomy bleeding when compared to children who have no increased post-operative T&A hemorrhage risk factors

# METHODOLOGY

- A retrospective chart review/case-control study was completed on all children receiving a T&A with a diagnosis of EDS and a random selection of over 25,000 patients without a diagnosis of EDS who received a T&A in the past 10 years at Children's Hospital of Colorado.
- Controls were excluded if they had a bleeding disorder or warranted admission after T&A based on the 2019 ENT clinical practice guidelines criteria(5).

# Bleeding risks associated with tonsillectomy in patients with **Ehlers-Danlos syndrome**

Jamil, Taylor L., MD, MPH<sup>1</sup>, Blades, Caitlin M., MS<sup>2</sup>, Chan, Kenny H., MD<sup>1</sup> <sup>1</sup>Department of Otolaryngology, Children's Hospital Colorado, Aurora, CO, USA <sup>2</sup>University of Colorado School of Medicine, Aurora, CO, USA

# **METHODOLOGY**

- Children undergoing a T&A for a diagnosis of periodic fever, aphthous stomatitis, pharyngitis and adenitis syndrome were also excluded. Bleeding risk in children with EDS was assessed by EDS subtype, prior
- echocardiograms, electrocardiograms, and laboratory data.

# RESULTS

| Variables               | Ehlers-Danlos syndrome |       | Control |       | Total  |       | p-value |
|-------------------------|------------------------|-------|---------|-------|--------|-------|---------|

\*\* noted that these patients were pre-emptively given amicar prior to T&A to use post operation to prevent a bleed. \*\*\* patient with factor replacement use had vWB disease

- both controls and EDS patients (p=0.609).
- (p<0.001).
- was no difference in bleeding risk.

- of hemorrhage.

# **RESULTS**

• Of 62 patients with EDS and 72 controls, those with EDS were more likely to be female (p=0.033), younger (p=0.051), and non-Hispanic white (p<0.001, p=0.01). Post-operative hemorrhage rates were unaffected by post-operative admission in

• EDS patients had no differences in blood loss during the T&A (p=0.669) and no significant risk of a post-operative hemorrhage (p=0.118).

• Isolated bleeding disorders did not increase postoperative hemorrhage

(p=0.092); however, EDS patients had more comorbid bleeding disorders

• When controlling the differences in the exposure and control population, there

# DISCUSSION

• Patients with EDS showed no significant increase in the risk of a posttonsillectomy hemorrhage when compared to children without EDS. • The combination of EDS, prior hemorrhage events, and comorbid bleeding disorders may elevate the risk of post-tonsillectomy hemorrhage. • Pre-operative optimization should be taken on a case-by-case basis. • If low risk pre-operatively, patients with EDS may not pose a significant risk
